ABSTRACT

Choices among young consumers are mainly driven by food preferences; in particular, a connection between appearance and acceptance of food has been highlighted, together with a general lack of knowledge of food processing. For these reasons, educational activities are important to increase scientific knowledge and awareness. The cheese-making educational laboratory described herein involved children, adolescents, and their parents/teachers in the preparation of fresh and naturally-coloured cheeses. At the end of the activity, both the colour preference and possible relation between preference and colour of cheese prepared were investigated administering a short questionnaire.

- Keywords: cheese preference, children food preference, colour preference, gender, neophobia, nutrition education -
INTRODUCTION

Food preference has a fundamental role in driving consumer’s choices and habits, especially in children (COOKE, 2007; NICKLAUS et al., 2004, LAUREATI et al., 2015a). Therefore, the number of food products specifically developed for children is growing and this market is acquiring increasing importance (ISSANCHOU, 2015).

Consequently, the youngest consumers are frequently involved in research and development programs, since their food habits will influence choices as they grow older and because their preferences, even if partly driven by advertisements (USTJANAUSKAS et al., 2014), seem to be strictly related to the sensory aspects of food (PAGLIARINI et al., 2005; MUSTONEN and TUORILA, 2010).

In 1994, Moskowitz (MOSKOWITS, 1994) highlighted how a visually pleasing product tends to be more appreciated by children, as visual attributes seem to be, among different sensory characteristics, those that mainly determine its success (KILDEGAARD et al., 2011; TOPCU, 2015). Indeed, children tend to create an “ideal picture” of each food product that can be related to their own idea of “good”; this picture represents a sort of reference point that can be used to dislike products whose appearance is not close to their expectation (MUSTONEN and TUORILA, 2009).

This phenomenon, called food neophobia, is defined as the fear of eating new or unfamiliar food (LINER and HOBDEN 1992) and is related to both the quality and variety of diet (LAUREATI et al., 2015b).

Nutritional education and food-related diseases prevention activities can be used for children and teenagers in order to: i) reduce the impact of poor food habits on health, and ii) avoid food neophobia, mainly responsible for refusing consumption of fruits and vegetables (WARDLE et al., 2003). Moreover, a lack of awareness of procedural knowledge, both in terms of food processing and nutritional values, must be taken into account (WORSLEY, 2002), highlighting the link between traditional food preparation and sensory properties (LAUREATI et al., 2006).

Nowadays, food education is mainly based on the social-cognitive theory (SCT) (BANDURA and ADAMS 1977), which incorporates the interaction of personal, environmental and behavioural factors. According to this theory, principles that are highly influential in establishing changing food behaviour in children are both models and repeated exposure.

Among the models, those that have been found to be effective in children include cartoon characters, peers, mothers, unfamiliar adults and teachers; moreover, children seem to be influenced more by the behaviour of multiple rather than single models (LOWE et al., 2004). Furthermore, according to Zajonc’s “mere exposure” theory (ZAJONC, 1968), repeated exposure to a specific food increases the liking and consumption of that food (COOKE et al., 2011; WARDLE et al., 2003B) through a mechanism that is believed to be a “learned safety” behaviour (KALAT and ROZIN, 1973). According to this theory, repeated ingestion of an unfamiliar food without negative consequences leads to increased acceptance of that food.

Several educational interventions for food have investigated all these factors, reporting promising results, especially for consumption of fruits and vegetables (EVANS et al., 2012; LAUREATI et al., 2014; REVERDY et al., 2008). Both principles of imitation and repeated exposure characterise food laboratories aimed at involving children in food preparation, thus familiarising them with food ingredients and technologies. Furthermore, it has been reported that the involvement of children in food preparation can contribute to increasing their acceptance for that food, according to the principle of repeated exposure (CHU et al., 2012).

For all these reasons, food educational interventions can play a relevant role in driving choice, interest and preference of children through better awareness of both sensory characteristics and technological process of traditional food products (MUSTONEN and TUORILA, 2010).

The educational cheese-making activity reported herein, called Cheese making in one hour, was conceived by a committee of referees as part of the Festival della Scienza 2014 (which took place in Genoa, Italy, from October 24 to November 2, 2014) and is considered as a “teaching tool” in order to increase scientific information about the cheese-making process.

This practical laboratory took the form of a family entertainment during which children and parents or teachers could share principles of traditional cheese making, spending some family or educational time away from daily work, but related to increased knowledge of food science.

The activity involved children, teenagers and adults (age from 6 to 87 years) in the traditional preparation of a fresh “primo sale like” cheese. Cheeses were naturally coloured (using turmeric, rocket and beetroot juice), and in order to keep the attention of participants, each was actively involved in the process by preparing his/her personal small cheese.

At the end of the activity, both the colour preference and possible relation between the colour of cheese prepared and preference were investigated by administration of a short and simple questionnaire.

MATERIALS AND METHODS

The cheese-making activity involved 738 participants (395 females and 343 males) with an age between 5 and 87 years and divided in groups of no more than 30 individuals. Both families and school classes could participate in the activity by asking the Festival staff to make

Cheese-making phases

1) Starter, rennet and milk natural flavouring

Fresh whole cow milk was heated to 36°C and 17 g/L of natural whole yoghurt was added as a starter. In order to produce coloured cheeses, different natural dyes were added (rocket, turmeric and beetroot juice) as reported in Table 1. While turmeric and beetroot juice were added to the milk 30 minutes after the addition of starter, together with 0.5 ml/L milk of liquid rennet (80% chymosin, 20% pepsin, provided by Graco), rocket was added during the last step of cheese shaping.

2) Curd cutting and synaeresis

After enzymatic coagulation, due to the addition of liquid curd, the gel obtained was cut into 4 x 4 cm squares, and 30 minutes later participants could observe the phenomena of curd synaeresis.

3) Curd breaking and purge

The squares of curd were broken into pieces of approximately 1.5 cm; during this phase, rocket was added (20 g/L milk) for preparation of green cheese.

4) Cheese shaping

Finally, the small pieces of curd were collected in dedicated shaper (60 g cheese shaper in polypropylene and polyethylene, Tecnolatte srl, Italy) by each participant as shown in Fig. 1.
5) Questionnaire

At the end of the cheese-making laboratory, each participant was administered a dedicated and simplified questionnaire. The questionnaire contained a first part regarding personal information: age and gender. Next, each participant was asked to provide information on: i) which colour of cheese he/she preferred and ii) which one he/she prepared. The filled questionnaires were collected in three dedicated paper boxes, one for each cheese colour.

STATISTICAL ANALYSIS

Preference data were analysed according to chi square test (p>0.05). Statistical analysis of data was carried out using the SAS/STAT statistical software package version 9.3.1. (SAS Institute Inc., Cary, USA).

RESULTS

The cheese-making laboratory was visited by 1900 participants. Many questionnaires were incomplete, while some participants preferred to not give their opinion. Data from 738 participants was collected considering the gender dimension and 5 age subgroups (1: 5-7 years old, 77 participants; 2: 8-10 years old, 142 participants; 3: 11-13 years old, 182 participants; 4: 14-18 years old, 203 participants; 5: >18 years old, 134 participants); subsequently, the visual preference for one of the three coloured cheeses was considered, as reported in Table 2. Data were divided in the 5 subgroups reported above, selected mainly according to different stages of cognitive development (GUINARD, 2001). In addition, different food preferences and consumption behaviour observed in these age groups confirmed that this type of age subdivision is relevant (LAUREATI et al., 2015).

Considering colour preference, regardless of age, the majority of participants preferred the white and green cheese (333 vs. 243 yellow and 162 pink; chi square=59.49; p<0.0001), which could be considered as the most “traditional” because it is present on the Italian market, rather than pink or yellow cheeses, and probably seen for the first time during the laboratory activity by the most of the respondents.

As reported in Table 2, sorting by age, it could be seen that the youngest participants (between 5 and 7 years old) chose the pink cheese as their favourite, while next oldest age subgroup (8 to 10 years) preferred yellow. Subjects from 11 years old and older chose the white and green cheese as their favourite, as did the overall population.

This result may be associated with both the attractive effect of colours on the children and to the tendency of the youngest, as observed by Moskowitz (MOSKOWITZ, 1994), to prefer food products with a pleasing appearance. Starting from the age of 11, children started to prefer, in accordance with adults, the white cheese mixed with rocket.

Moreover, the youngest children’s preference can be explained by food neophobia, which is particularly high for fruits and vegetables, reaching its highest level between 2 and 6 years (PEL-CHAT and PLINER, 1995; PLINER, 1994; PLINER and LOEWEN, 1997; LAUREATI et al., 2015c). It then tends to decrease when children move towards adolescence (ADDRESSI et al., 2005), finally becoming relatively stable in adulthood, probably because of an increased number of food experiences (COOKE and WARDLE, 2005).

On the other hand, the preference of older respondents for a white cheese enriched with a vegetable (rocket), may be linked to a low acceptance of adults for an innovative food, while its dislike among the younger interviewees could be related to the visual presence of rocket inside cheese (RUSSEL and WORSLEY, 2008; LAUREATI et al., 2015).

It has already been demonstrated that traditional food products have been always recognised by consumers as linked to a specific geographical origin and highest sensory quality (GUERRERO et al., 2009); as a consequence, this cheese was probably considered much more similar to product already on the Italian market compared to the pink and yellow ones.

Sorting by gender (Table 3), no differences in preferences were seen regarding the white and green cheese, except for the oldest group (>18 years). A clear gender-related difference was, however, found for the pink and the yellow cheeses: the former seemed to be much more appreciated by females (all age classes except 14−18 years, but only if p<0.10 is considered as marginally significant), while the latter was favoured among males (especially from 8-10, 14-18).

In order to determine if this could influence the visual preference of participants, they were also questioned about the colour of the cheese they prepared; however, a significant association between cheese preferred and colour preference for one of the three coloured cheeses was not seen, even if some significant differences were seen among the youngest consumers (Table 4).

In particular, when sorting by age, the subgroup from 8 to 10 years who prepared the yellow cheese more frequently preferred this cheese over the others (26 of 52, chi square=7.5 p=0.02). Likewise, the subgroup from 5 to 7 years who prepared the pink cheese preferred it more frequently than others (12 of 21 choices, chi square=7.1 p=0.03). However, the older participants did not show a consistent trend of preferred cheese over than prepared.

Data from literature suggest that 7–8 exposures are needed to produce a learning effect.
that can influence consumer appreciation regarding a product (MAIER et al., 2007). Thus, it might well be that the single exposure during the cheese-making educational activity was not enough to influence children choice.

CONCLUSIONS

The results of this study highlight how visual preference for a food, in terms of colour, changes during different stages of life. Indeed, the data demonstrates how children can be influenced by food appearance and how the aspect of a product can be related to its acceptance, especially among younger individuals; in fact, the youngest participants tended to prefer intensively coloured cheese vs. the white and green version, probably because of the presence of rocket. Moreover, the cheese-making laboratory was considered to be a useful tool in order to catch and keep participants’ attention, involving them in a practical activity while sharing educational and scientific information related both to food processing (fresh cheese production) and sensory (visual) aspects.

ACKNOWLEDGMENTS

The activity described in this work was made possible by the kind permission of Festival della Scienza. A special thanks goes to Emanuele Bargelli, events Creator & Coordinator for Festival della Scienza.
